ABSTRACT

Complete data from 30 rocket-borne experiments at Wallops Island, Virginia, Churchill, Manitoba, Canada, and Ascension Island in the South Atlantic Ocean are presented. Temperatures, pressures, densities, and wind velocities have been derived from recorded times of explosions and sound arrivals in the grenade experiment and from impact and static pressure measurements in the pitot-static tube experiment, but no attempt has been made to analyze the meteorological significance of these measurements. Error analyses are included for the results of each of the 27 grenade experiments. Tabulated grenade experiment results from Churchill in 1956 to 1958 and Guam in 1958 are presented as an appendix.

Goddard Space Flight Center

INTRODUCTION

In 1964 a total of 30 rocket grenade and pitot-static tube experiments were performed at Wallops Island, Virginia, Churchill, Canada, and Ascension Island, in the South Atlantic Ocean, by Goddard Space Flight Center. This report presents the data obtained in these experiments; however, these data have not been analyzed for their meteorological significance. Rather, this report should be considered as a record of the unsmoothed, raw measurements which may serve as the basis of further investigation and interpretation of the structure of the atmosphere.

Also included as an appendix to this report are the grenade experiment data taken at Churchill from 1956 to 1958 (Reference 1) and at Guam in 1958 (Reference 2). A complete tabulation of these data has not been previously published.

The grenade experiment and pitot-static tube experiment are two of the several techniques employed in the NASA Meteorological Sounding Rocket Program, the objective of which is to obtain as representative as possible a synoptic sample of the structure of the mesosphere and lower ionosphere. In order to extend the findings over the widest possible geographic area, to permit more accurate analyses, and perhaps eventually to achieve a global network of data stations, the NASA soundings are coordinated with soundings in other parts of the world whenever possible. The details of the instrumentation and data processing used in this program have been thoroughly described elsewhere (References 3 and 4).

EXPERIMENTAL METHODS

In the grenade experiment, 1-, 2-, and 3-pound explosive charges (grenades) are carried aloft in the nose cone of a Nike-Cajun sounding rocket. The grenades are ejected and exploded at 4- to 6-kilometer intervals. The rocket position and hence the exact position of the explosion are determined by a precision radar such as the FPS-16, a Doppler tracking system, or both. The time of the explosion is detected by small rocket-borne infrared photocells and telemetered to the

ground. A ground-based array of hot-wire microphones with frequency response peaked at 4 cycles per second is used to detect and record the sound waves from each exploding grenade. The measured experimental parameters are the times of the grenade explosions, the positions of the grenade explosions, and the times of arrival of the sound waves at the ground-based microphones.

Elevation and azimuth angles are computed for each arriving sound wave front by applying a least-squares fit to the arrival times at the various microphones. Each wave is then analytically traced up through the atmosphere by means of Snell's law. Data from radiosonde ascents or from small meteorological rockets obtained at the time of the grenade soundings are used for this tracing up to the first explosion; above this, the results of the experiment itself are used for each successive explosion. This apparent position of the wave is then compared with the known position of the wave source, the grenade explosion. The amount by which the sound wave has been displaced horizontally from one explosion to the next is a measure of the average wind velocity vector in the layer between any two adjacent explosions. The average speed of sound and hence the average temperature between two adjacent explosions may also be determined. The temperature profile consists of discrete points; each point represents an average value for an altitude layer between consecutive grenade explosions. The temperature profile is used to derive pressure and density profiles from the pressure at the highest radiosonde altitude. This reference pressure is available from the accompanying radiosonde and small meteorological rocketsonde (Reference 5). Pressure is calculated by use of the hydrostatic equation and the equation of state; an integration is performed over the temperature profile starting at the known pressure. The density at any level is then computed from the pressure, temperature, and universal gas constant.

In the pitot-static tube experiment, two radioactive ionization pressure gages are installed in the payload so that well-established aerodynamic relationships permit these gages to measure density and ambient pressure as the Nike-Apache rocket ascends. The gage outputs are telemetered to ground-based receiving and recording equipment. A trajectory of the rocket is provided by radar tracking, Doppler tracking, or both to determine the altitude of the measurements. The measured experimental parameters are ram pressure, static pressure, and velocity and position of the payload in space. The ram pressure is related to density by the Rayleigh equation and the equation of state in the continuum region and by a modified thermal transpiration equation in the free-molecular-flow region. The ambient pressure is measured directly in the continuum region and is corrected for the thermal transpiration effect in the free-molecular-flow region. The temperature profile can be computed utilizing the pressure and density profiles and the equation of state or by integrating density using a form of the hydrostatic equation.

The rocket-borne experiments were launched from three sites: Ascension Island (8°S, 14°W), Churchill (59°N, 94°W), and Wallops Island (38°N, 75°W) because they represent typical equatorial, subarctic, and temperate locations, respectively. Table 1 summarizes the time, date, and site of each sounding. Seven soundings (four grenades and three pitot-tubes) were made at Ascension Island, seven soundings (grenades) were made at Churchill, and sixteen soundings (grenades) were made at Wallops Island. The Ascension Island soundings include a day-night pair of profiles

*These experiments were performed by the University of Michigan, J. Horvath, principal investigator, under contract to GSFC.

on 15 April and the Wallops Island soundings include four profiles made during a 17-hour period on 5 and 6 November, which were intended to observe diurnal variations. Six soundings were made nearly simultaneously from Ascension Island, Churchill, and Wallops Island. In addition, four nearly simultaneous soundings were made from Ascension and Wallops Islands and eight were made from Churchill and Wallops Island.

RESULTS

The results of the 30 soundings are presented in Figures 1 through 30. In the grenade experiment results, the directly measured parameters of temperature and wind are tabulated in computer printout form (left-hand page). Tables of interpolated temperature, computed pressure, percent

pressure deviation from the 1962 U.S. standard atmosphere (Reference 6), computed density, and percent density deviation from the standard atmosphere as a function of height are tabulated (right-hand page). The winds at five kilometer intervals are tabulated in component form; these components are linear interpolations of the measured winds. The individual errors in the measured winds and temperatures are also tabulated. The pitot-tube results present measured pressure and density and derived temperature. The pressure and density deviations from the 1962 U.S. standard atmosphere (Reference 6) are tabulated with the measured data.

ERROR ANALYSIS

An error analysis has been run on an LGP 30 computer for all the grenade temperatures and winds reported herein. It was determined by the previous error analysis published in Reference 7 that more than 90 percent of the experimental error is due to the inaccuracy in the determination of the sound arrival times at the various microphones, which produces errors in the computed azimuth and zenith angles of the sound wave. Thus, by treating only azimuth and zenith errors, a good approximation to the total error was obtained.

The following procedure was utilized to obtain the azimuth and zenith errors: Four independent readings of the sound arrival time at each microphone were obtained for each grenade explosion. The average of these readings was then used to obtain a least-squares fit for a spherical sound wave with a radius equal to the distance between the explosion and the microphone array. The least-squares fit provides azimuth and zenith angles and their standard deviations for each grenade.

The problem of obtaining the wind and temperature errors was then broken into two parts. Separate calculations were made, first for the even layers between grenades and then for the odd layers. For each layer a single azimuth and zenith deviation was computed from the formulas

$$\sigma_{az} = \sqrt{\sigma_{az_U}^2 + \sigma_{az_L}^2}$$

and

$$\sigma_{zen} = \sqrt{\sigma_{zen_U}^2 + \sigma_{zen_L}^2}$$

where the subscripts U and L indicate the azimuth and zenith deviations for the upper and lower grenades bounding a given layer. The calculation is divided into two sections so that the deviations of one layer will not influence the temperature and wind of any other layer significantly.

The error for a given temperature point was computed from the formula

$$\text{Temperature error} = \sqrt{(\Delta T_{az})^2 + (\Delta T_{zen})^2}$$

where ΔT_{az} is the change in the temperature induced by the azimuth deviation alone and ΔT_{zen} is the change in temperature caused by the zenith deviation alone. A similar formula holds for the wind.

ACKNOWLEDGMENTS

The authors greatly appreciate the contributions of Texas Western College in conducting the sound-range portion of this experiment; the New Mexico State University for the operation of the Doppler tracking system; and the NASA Wallops Station, the Rocket Research Facility at Churchill, and the Eastern Test Range at Ascension Island for the range support they provided.

(Manuscript received March 10, 1966)

"The aeronautical and space activities of the United States shall be conducted so as to contribute . . . to the expansion of human knowledge of phenomena in the atmosphere and space. The Administration shall provide for the widest practicable and appropriate dissemination of information concerning its activities and the results thereof."

—NATIONAL AERONAUTICS AND SPACE ACT OF 1958

NASA SCIENTIFIC AND TECHNICAL PUBLICATIONS

TECHNICAL REPORTS: Scientific and technical information considered important, complete, and a lasting contribution to existing knowledge.

TECHNICAL NOTES: Information less broad in scope but nevertheless of importance as a contribution to existing knowledge.

TECHNICAL MEMORANDUMS: Information receiving limited distribution because of preliminary data, security classification, or other reasons.

CONTRACTOR REPORTS: Technical information generated in connection with a NASA contract or grant and released under NASA auspices.

TECHNICAL TRANSLATIONS: Information published in a foreign language considered to merit NASA distribution in English.

TECHNICAL REPRINTS: Information derived from NASA activities and initially published in the form of journal articles.

SPECIAL PUBLICATIONS: Information derived from or of value to NASA activities but not necessarily reporting the results of individual NASA-programmed scientific efforts. Publications include conference proceedings, monographs, data compilations, handbooks, sourcebooks, and special bibliographies.

Details on the availability of these publications may be obtained from:
